DESCRIPTION

NOVEL HYBRID PESTICIDAL TOXINS

Cross-Reference to a Related Application

This is a continuation-in-part of co-pending application Serial No. 07/187,167, filed on August 28, 1988.

Background of the Invention

Bacillus thuringiensis (B.t.) is widely used for the microbial control of insects. The active component has been identified as a proteinaceous paraspore also described as a crystal. Following ingestion by the insect host the crystal is processed by gut proteases to the active protease-resistant form which is toxic. Toxicity is postulated to follow binding of the active form of the toxin to the insect cells resulting in disruption of cellular integrity through a receptor mediated process (Knowles, B.H. et al. [1984] FEBS 168:197-202).

A comparison of amino acid sequence for the protease activated form of *B. thuringiensis* var. *kurstaki* HD-1 and HD-73 reveals that the amino-terminal (N-terminal) half of the protein is highly conserved whereas the carboxy-terminal (C-terminal) is highly substituted in sequence. In U.S. Patent 4,467,036 *B. thuringiensis* var. *kurstaki* HD-1 is disclosed as being available from the NRRL culture repository at Peoria, IL. Its accession number is NRRL B-3792. *B. thuringiensis* var. *kurstaki* HD-73 is also available from the NRRL under accession number NRRL B-4488.

In addition to HD-1 and HD-73, the presence of an N-terminal conserved or constant region and a C-terminal highly substituted or variable region in the active toxin has been demonstrated for *B. thuringiensis* var. *berliner* and var. *aizawa*.

Schnepf, E.H. and Whitely, H.R. (1985) J. Biol. Chem. 260:6273-6290 have demonstrated that deletions of the amino and carboxy termini result in a loss of toxicity indicating that both regions of the active toxin are required for toxicity.

Brief Summary of the Invention

The subject invention concerns novel hybrid pesticidal toxins. Specifically exemplified is an insecticidal fusion protein expressed as a single polypeptide product of a hybrid gene comprising a cytotoxic agent and a specific insect gut cell recognition ("binding") protein to direct the cytotoxic agent to the host target. Details for the construction of a hybrid *B.t.* toxin are disclosed. The cytotoxic agent is an ADP-ribosylating enzyme. For example, the cytotoxic agent can be the A fragment of the diphtheria toxin, plus the B fragment of the diphtheria toxin which has been truncated at the carboxyl-terminus to remove the eukaryotic binding region. The diphtheria toxin gene 3' recognition domain is replaced with a synthetic DNA linker region to which a gene encoding the insect gut epithelial cell recognition portion of *Bacillus thuringiensis* var. *kurstaki* HD-73 is ligated.

The purpose of the synthetic DNA linker is to join pieces of otherwise non-ligating segments of DNA. In the subject invention, it is a critical element of the invention because it must be of a suitable length and amino acid composition to minimize susceptibility to insect protease cleavage. Thus, the peptide linker should be as short as possible, e.g., four or less amino acids, and it should not contain lysine residues. There are other considerations in the use of a suitable linker. For example, the linker should maintain the correct reading frame and it should maintain a continuum in the hydropathy profile of the primary structure of the protein.

The novel hybrid *B.t.* gene can be transformed into a suitable host to produce the toxin which can be recovered by standard biochemical procedures. Alternatively, the transformed host containing the novel hybrid *B.t.* gene can be used *per se* as an insecticide, as disclosed hereinafter. Though *B.t.k.* HD-73 is specifically exemplified herein, the invention includes other microbial insecticides.

Table 1 gives molecular weights of polypeptides present in SeNPV and HzNPV LOVAL preparations determined from relative electrophoretic mobilities.

Table 2 shows hybrid virus infectivity.

Table 3 gives relative molecular weights of polypeptides as determined by electrophoretic mobility.

The process, described herein, can be applied to the C-terminal variable portion of active *B. thuringiensis* toxins other than var. *kurstaki* HD-73. These include those *B.t.*'s which possess a variable region in the C-terminal half of the active toxin. Examples of such *B.t.*'s are *B.t.* var. *israelensis*, active against mosquitoes; *B.t.* var. *san diego* and *B.t.* var. *tenebrionis*, active against coleoptera; and *B. sphaericus*, active against mosquito larvae. Cultures exemplifying the above are as follows:

Bacillus thuringiensis var. kurstaki HD-1--NRRL B-3792; disclosed in U.S. Patent 4,448,885

Bacillus thuringiensis var. israelensis--ATCC 35646

Bacillus thuringiensis var. san diego--NRRL B-15939

The following *B. thuringiensis* cultures are available from the United States Department of Agriculture (USDA) at Brownsville, Texas. Requests should be made to Joe Garcia, USDA, ARS, Cotton Insects Research Unit, P.O. Box 1033, Brownsville, Texas 78520 USA.

The technology of the invention is not limited to the use of diphtheria toxin as the cytotoxic agent as a variety of enzymes that inhibit protein synthesis can be used, for example, the ribosome inactivators such as ricin, dianthin, saporin, gelonin, tritin, abrin, and modeccin, as well as enzymes from barley seeds, rye seeds, wild beans, and corn seeds (see Stripe, F., and Barbieri, L., [1986] FEBS 195:1-8).

The subject invention is not limited to toxins active against insects, but also includes *B. thuringiensis* toxins active against animal parasitic nematodes, and plant parasitic nematodes. In general, any pesticide can be used. For example, it can be a polypeptide which has toxic activity toward a eukaryotic multicellular pest, such as insects, e.g., coleoptera, lepidoptera, diptera, hemiptera, dermaptera, and orthoptera; or arachnids; gastropods; or worms, such as nematodes and platyhelminths. Various susceptible insects include beetles, moths, flies, grasshoppers, lice, and earwigs.

The subject invention also includes a process for altering the insect host range of a nuclear polyhedrosis virus (NPV) by re-associating solubilized envelope proteins from one occluded NPV to another to produce a hybrid virus having an altered NPV insect host range.

The one-letter symbol for the amino acids used in SEQ ID 3 and 4 is well known in the art. For convenience, the relationship of the three-letter abbreviation and the one-letter symbol for amino acids is as follows:

Ala	A	Leu	L
Arg	R	Lys	K
Asn	N	Met	M
Asp	D	Phe	F

LOVAL was suspended in buffer containing 40 mM Tris-acetate, 1 mM EDTA, pH 8.0 (TAE). Octyl glucoside was added at a ratio of 1:2 (w/w) and the mixture was incubated for 4 hours at 37°C with constant shaking at 200 rpm. Non-solubilized viral protein was removed by centrifugation at 100,000 g for 1 hr at 4°C. The supernatant was dialyzed with HzNPV LOVAL at a ration of 1:1 (w/w) for 24 hours against 3 changes of TAE buffer. The dialysate was centrifuged at 100,000 g for 1 hr at 4°C. The supernatant was discarded and the pellet containing the hybrid virus (Se*HzNPV) was resuspended in TAE buffer to be used in bioassay or for analysis by SDS-PAGE.

In order to determine which of the three polypeptides extracted by octyl glucoside solubilization of SeNPV was responsible for conferring virulence to the HzNPV hybrid virus (Se*HzNPV) to <u>Spodoptera exigua</u> the following experiment was performed: The three SeNPV proteins extracted by octyl glucoside were labeled with ¹²⁵I. The hybrid virus was prepared as described using the radiolabeled proteins and unlabeled HzNPV. An autoradiogram of an SDS-polyacrylamide gel of the hybrid virus showed all three proteins to be associated with HzNPV.

Detailed Description of the Invention

Novel hybrid toxins are produced by fusion of a pesticidal toxin to a cytotoxic agent. Specifically exemplified herein is a hybrid *B.t.* toxin prepared by fusion of the insect gut epithelial cell recognition region of a *B.t.* gene to diphtheria toxin B chain.

The hybrid toxin gene of the subject invention can be introduced into a wide variety of microbial hosts. Expression of the toxin gene results, directly or indirectly, in the intracellular production and maintenance of the pesticide. With suitable hosts, e.g., *Pseudomonas*, the microbes can be applied to the situs of coleopteran insects where they will proliferate and be ingested by the insects. The result is a control of the unwanted insects. Alternatively, the microbe hosting the toxin gene can be treated under conditions that prolong the activity of the toxin produced in the cell. The treated cell then can be applied to the environment of target pest(s). The resulting product retains the toxicity of the *B.t.* toxin.

Where the *B.t.* toxin gene is introduced via a suitable vector into a microbial host, and said host is applied to the environment in a living state, it is essential that certain host microbes be used. Microorganism hosts are selected which are known

10

5

15

20

to occupy the "phytosphere" (phylloplane, phyllosphere, rhizosphere, and/or rhizoplane) of one or more crops of interest. These microorganisms are selected so as to be capable of successfully competing in the particular environment (crop and other insect habitats) with the wild-type microorganisms, provide for stable maintenance and expression of the gene expressing the polypeptide pesticide, and, desirably, provide for improved protection of the pesticide from environmental degradation and inactivation.

A large number of microorganisms are known to inhabit the phylloplane (the surface of the plant leaves) and/or the rhizosphere (the soil surrounding plant roots) of a wide variety of important crops. These microorganisms include bacteria, algae, and fungi. Of particular interest are microorganisms, such as bacteria, e.g., genera Pseudomonas, Erwinia, Serratia, Klebsiella, Xanthomonas, Streptomyces, Rhizobium, Rhodopseudomonas, Methylophilius, Agrobacterium, Acetobacter, Lactobacillus, Arthrobacter, Azotobacter, Leuconostoc, and Alcaligenes; fungi, particularly yeast, e.g., genera Saccharomyces, Cryptococcus, Kluyveromyces, Sporobolomyces, Rhodotorula, and Aureobasidium. Of particular interest are such phytosphere bacterial species as Pseudomonas syringae. Pseudomonas fluorescens, Serratia marcescens, Acetobacter xylinum, Agrobacterium tumefaciens, Rhodopseudomonas spheroides, Xanthomonas campestris, Rhizobium melioti, Alcaligenes entrophus, and Azotobacter vinlandii; and phytosphere yeast species such as Rhodotorula rubra, R. glutinis, R. marina, R. aurantiaca, Cryptococcus albidus, C. diffluens, C. laurentii, Saccharomyces rosei, S. pretoriensis, S. cerevisiae, Sporobolomyces roseus, S. odorus, Kluyveromyces veronae, Of particular interest are the pigmented and Aureobasidium pollulans. microorganisms.

A wide variety of ways are available for introducing the B.t. gene expressing the toxin into the microorganism host under conditions which allow for stable maintenance and expression of the gene. One can provide for DNA constructs which include the transcriptional and translational regulatory signals for expression of the toxin gene, the toxin gene under their regulatory control and a DNA

10

5

15

HIS HOTTON

'nβ

1

F

...

: # ľ,

20

sequence homologous with a sequence in the host organism, whereby integration will occur, and/or a replication system which is functional in the host, whereby integration or stable maintenance will occur.

The transcriptional initiation signals will include a promoter and a transcriptional initiation start site. In some instances, it may be desirable to provide for regulative expression of the toxin, where expression of the toxin will only occur after release into the environment. This can be achieved with operators or a region binding to an activator or enhancers, which are capable of induction upon a change in the physical or chemical environment of the microorganisms. For example, a temperature sensitive regulatory region may be employed, where the organisms may be grown up in the laboratory without expression of a toxin, but upon release into the environment, expression would begin. Other techniques may employ a specific nutrient medium in the laboratory, which inhibits the expression of the toxin, where the nutrient medium in the environment would allow for expression of the toxin. For translational initiation, a ribosomal binding site and an initiation codon will be present.

Various manipulations may be employed for enhancing the expression of the messenger, particularly by using an active promoter, as well as by employing sequences, which enhance the stability of the messenger RNA. The initiation and translational termination region will involve stop codon(s), a terminator region, and optionally, a polyadenylation signal.

In the direction of transcription, namely in the 5' to 3' direction of the coding or sense sequence, the construct will involve the transcriptional regulatory region, if any, and the promoter, where the regulatory region may be either 5' or 3' of the promoter, the ribosomal binding site, the initiation codon, the structural gene having an open reading frame in phase with the initiation codon, the stop codon(s), the polyadenylation signal sequence, if any, and the terminator region. This sequence as a double strand may be used by itself for transformation of a microorganism host, but will usually be included with a DNA sequence involving a marker, where the

5

10

15

11.11.11

1 🚅

1 20

second DNA sequence may be joined to the toxin expression construct during introduction of the DNA into the host.

By a marker is intended a structural gene which provides for selection of those hosts which have been modified or transformed. The marker will normally provide for selective advantage, for example, providing for biocide resistance, e.g., resistance to antibiotics or heavy metals; complementation, so as to provide prototropy to an auxotrophic host, or the like. Preferably, complementation is employed, so that the modified host may not only be selected, but may also be One or more markers may be employed in the competitive in the field. development of the constructs, as well as for modifying the host. The organisms may be further modified by providing for a competitive advantage against other wild-type microorganisms in the field. For example, genes expressing metal chelating agents, e.g., siderophores, may be introduced into the host along with the structural gene expressing the toxin. In this manner, the enhanced expression of a siderophore may provide for a competitive advantage for the toxin-producing host, so that it may effectively compete with the wild-type microorganisms and stably occupy a niche in the environment.

Where no functional replication system is present, the construct will also include a sequence of at least 50 basepairs (bp), preferably at least about 100 bp, and usually not more than about 1000 bp of a sequence homologous with a sequence in the host. In this way, the probability of legitimate recombination is enhanced, so that the gene will be integrated into the host and stably maintained by the host. Desirably, the toxin gene will be in close proximity to the gene providing for complementation as well as the gene providing for the competitive advantage. Therefore, in the event that a toxin gene is lost, the resulting organism will be likely to also lose the complementing gene and/or the gene providing for the competitive advantage, so that it will be unable to compete in the environment with the gene retaining the intact construct.

A large number of transcriptional regulatory regions are available from a wide variety of microorganism hosts, such as bacteria, bacteriophage, cyanobacteria,

5

10

15

11

ıμ

20

25

algae, fungi, and the like. Various transcriptional regulatory regions include the regions associated with the <u>trp</u> gene, <u>lac</u> gene, <u>gal</u> gene, the lambda left and right promoters, the Tac promoter, the naturally-occurring promoters associated with the toxin gene, where functional in the host. See for example, U.S. Patent Nos. 4,332,898, 4,342,832 and 4,356,270. The termination region may be the termination region normally associated with the transcriptional initiation region or a different transcriptional initiation region, so long as the two regions are compatible and functional in the host.

Where stable episomal maintenance or integration is desired, a plasmid will be employed which has a replication system which is functional in the host. The replication system may be derived from the chromosome, an episomal element normally present in the host or a different host, or a replication system from a virus which is stable in the host. A large number of plasmids are available, such as pBR322, pACYC184, RSF1010, pRO1614, and the like. See for example, Olson et al., (1982) J. Bacteriol. 150:6069, and Bagdasarian et al., (1981) Gene 16:237, and U.S. Patent Nos. 4,356,270, 4,362,817, and 4,371,625.

The B.t. gene can be introduced between the transcriptional and translational initiation region and the transcriptional and translational termination region, so as to be under the regulatory control of the initiation region. This construct will be included in a plasmid, which will include at least one replication system, but may include more than one, where one replication system is employed for cloning during the development of the plasmid and the second replication system is necessary for functioning in the ultimate host. In addition, one or more markers may be present, which have been described previously. Where integration is desired, the plasmid will desirably include a sequence homologous with the host genome.

The transformants can be isolated in accordance with conventional ways, usually employing a selection technique, which allows for selection of the desired organism as against unmodified organisms or transferring organisms, when present. The transformants then can be tested for pesticidal activity.

-

5

10

15

...

20

Suitable host cells, where the pesticide-containing cells will be treated to prolong the activity of the toxin in the cell when the then treated cell is applied to the environment of target pest(s), may include either prokaryotes or eukaryotes, normally being limited to those cells which do not produce substances toxic to higher organisms, such as mammals. However, organisms which produce substances toxic to higher organisms could be used, where the toxin is unstable or the level of application sufficiently low as to avoid any possibility of toxicity to a mammalian As hosts, of particular interest will be the prokaryotes and the lower eukaryotes, such as fungi. Illustrative prokaryotes, both Gram-negative and positive, include Enterobacteriaceae, such as Escherichia, Erwinia, Shigella, Salmonella, and Proteus; Bacillaceae; Rhizobiceae, such as Rhizobium; Spirillaceae, such as photobacterium, Zymomonas, Serratia, Aeromonas, Vibrio, Desulfovibrio, Spirillum; Lactobacillaceae; Pseudomonadaceae, such as Pseudomonas and Acetobacter; Azotobacteraceae and Nitrobacteraceae. Among eukaryotes are fungi, such as Phycomycetes and Ascomycetes, which includes yeast, such as Saccharomyces and Schizosaccharomyces; and Basidiomycetes yeast, such as Rhodotorula, Aureobasidium, Sporobolomyces, and the like.

Characteristics of particular interest in selecting a host cell for purposes of production include ease of introducing the *B.t.* gene into the host, availability of expression systems, efficiency of expression, stability of the pesticide in the host, and the presence of auxiliary genetic capabilities. Characteristics of interest for use as a pesticide microcapsule include protective qualities for the pesticide, such as thick cell walls, pigmentation, and intracellular packaging or formation of inclusion bodies; leaf affinity; lack of mammalian toxicity; attractiveness to pests for ingestion; ease of killing and fixing without damage to the toxin; and the like. Other considerations include ease of formulation and handling, economics, storage stability, and the like.

Host organisms of particular interest include yeast, such as *Rhodotorula* sp., *Aureobasidium* sp., *Saccharomyces* sp., and *Sporobolomyces* sp.; phylloplane

5

10

15

1

: 🗗

£ 20

organisms such as *Pseudomonas* sp., *Erwinia* sp. and *Flavobacterium* sp.; or such other organisms as *Escherichia*, *Lactobacillus* sp., *Bacillus* sp., and the like. Specific organisms include *Pseudomonas aeruginosa*, *Pseudomonas fluorescens*, *Saccharomyces cerevisiae*, *Bacillus thuringiensis*, *Escherichia coli*, *Bacillus subtilis*, and the like.

The cell will usually be intact and be substantially in the proliferative form when treated, rather than in a spore form, although in some instances spores may be employed.

Treatment of the microbial cell, e.g., a microbe containing the B.t. toxin gene, can be by chemical or physical means, or by a combination of chemical and/or physical means, so long as the technique does not deleteriously affect the properties of the toxin, nor diminish the cellular capability in protecting the toxin. Examples of chemical reagents are halogenating agents, particularly halogens of atomic no. 17-80. More particularly, iodine can be used under mild conditions and for sufficient time to achieve the desired results. Other suitable techniques include treatment with aldehydes, such as formaldehyde and glutaraldehyde; anti-infectives, such as zephiran chloride and cetylpyridinium chloride; alcohols, such as isopropyl and ethanol; various histologic fixatives, such as Bouin's fixative and Helly's fixative (See: Humason, Gretchen L., Animal Tissue Techniques, W.H. Freeman and Company, 1967); or a combination of physical (heat) and chemical agents that preserve and prolong the activity of the toxin produced in the cell when the cell is administered to the host animal. Examples of physical means are short wavelength radiation such as gamma-radiation and X-radiation, freezing, UV irradiation, lyophilization, and the like.

The cells generally will have enhanced structural stability which will enhance resistance to environmental conditions. Where the pesticide is in a proform, the method of inactivation should be selected so as not to inhibit processing of the proform to the mature form of the pesticide by the target pest pathogen. For example, formaldehyde will crosslink proteins and could inhibit processing of the

10

5

15

#.#

÷

1

€ 20

proform of a polypeptide pesticide. The method of inactivation or killing retains at least a substantial portion of the bio-availability or bioactivity of the toxin.

The cellular host containing the B.t. insecticidal gene may be grown in any convenient nutrient medium, where the DNA construct provides a selective advantage, providing for a selective medium so that substantially all or all of the cells retain the B.t. gene. These cells may then be harvested in accordance with conventional ways. Alternatively, the cells can be treated prior to harvesting.

The B.t. cells may be formulated in a variety of ways. They may be employed as wettable powders, granules or dusts, by mixing with various inert materials, such as inorganic minerals (phyllosilicates, carbonates, sulfates, phosphates, and the like) or botanical materials (powdered corncobs, rice hulls, walnut shells, and the like). The formulations may include spreader-sticker adjuvants, stabilizing agents, other pesticidal additives, or surfactants. Liquid formulations may be aqueous-based or non-aqueous and employed as foams, gels, suspensions, emulsifiable concentrates, or the like. The ingredients may include rheological agents, surfactants, emulsifiers, dispersants, or polymers.

The pesticidal concentration will vary widely depending upon the nature of the particular formulation, particularly whether it is a concentrate or to be used directly. The pesticide will be present in at least 1% by weight and may be 100%by weight. The dry formulations will have from about 1-95% by weight of the pesticide while the liquid formulations will generally be from about 1-60% by weight of the solids in the liquid phase. The formulations will generally have from about 10² to about 10⁴ cells/mg. These formulations will be administered at about 50 mg (liquid or dry) to 1 kg or more per hectare.

The formulations can be applied to the environment of the coleopteran pest(s), e.g., plants, soil or water, by spraying, dusting, sprinkling, or the like.

Following are examples which illustrate procedures, including the best mode, for practicing the invention. These examples should not be construed as limiting. All percentages are by weight and all solvent mixture proportions are by volume unless otherwise noted.

Example 1 – Construction of a Hybrid Toxin Containing Near-Full Length B.t. Toxin Fused to Diphtheria Toxin B-Chain ("Full Length toxin")

A partial restriction endonuclease map of MR436 protoxin coding sequence is depicted in Figures 1A and 1B. Protein coding sequences from the initiator methionine to beyond the XhoI site were derived from B.t. strain HD-73 toxin. Approximately half of the protoxin at the amino-terminal end corresponds to active toxin. For HD-73, the XhoI site conveniently separates toxin and protoxin sequences. A fragment from plasmid MR436, containing nearly full-length HD-73 toxin coding sequences, was isolated by NsiI and XhoI double-digestion and gelpurification. This fragment contains amino acids (AA) cys¹⁰ to glu⁶¹³ of HD-73 (Adang, M.J. et al. [1985] Gene 36:289-300). Plasmid pBC508 (see Murphy, J.R. et al. [1986] Proc. Nat. Acad. Sci. USA 83:8252-8262, for restriction map) which contains the B-chain of diphtheria toxin, was digested with SphI and HindIII. The SphI site of digested, gel-purified pBC508 (minus the small SphI-HindIII fragment) was joined to the NsiI site of HD-73 DNA using a synthetic DNA oligonucleotide adaptor set:

5' - CAGGTTGCA-3'

3' - GTACGTCCA-5'

The adapters regenerate the <u>Sph</u>I site, eliminate the <u>Nsi</u>I site, maintain the correct translation reading frame, and add two amino acids (ala-gly) between diphtheria toxin B-chain his⁴⁸⁴ and HD-73 cys¹⁰. The details of the fusion junction, with the adapters boxed, are shown below:

Example 2 – Construction of Hybrid Toxin Clones Containing Shorter Lengths of HD-73 Coding Sequence Fused to Diphtheria Toxin B-Chain ("Half-length hybrid toxin" and "Quarter-length hybrid toxin")

Plasmid p26, described above, served as the substrate for additional hybrid toxin constructions. Two constructs were generated which either fuse His⁴⁸⁴ of diphtheria toxin B-chain to amino acids Arg²⁵⁸ through Glu⁶¹³ of HD-73 (plasmid construct p151, coding for the "half-length" hybrid toxin), or His⁴⁸⁴ of diphtheria toxin B-chain to amino acid Ala⁴⁵⁰ through Glu⁶¹³ of HD-73 (plasmid construct p11, coding for the "quarter-length" hybrid toxin). Hybrid toxin plasmid p151 was generated by restriction digestion of p26 with SphI and AsuII, gel-purification of the DNA fragment containing pBC508 plus HD-73 coding for Arg²⁵⁸ through the synthetic XhoI-HindIII adaptor (described above), and re-ligation of the SphI to the AsuII site with a synthetic oligonucleotide adaptor set of the sequence:

Example 3 – Construction of Hybrid Toxin Expression Vectors Containing Fused Coding Sequences for Diphtheria Toxin A-Chain and Truncated B-Chain and HD-73

HD-73 coding sequence DNA fragments were excised from plasmids p26, p151, and p11 by digestion with SphI and SalI, and gel-purified. These gel-purified fragments were used for construction of a hybrid toxin expression vector containing diphtheria toxin A and B-chains and HD-73 coding sequences. Assembly of the hybrid toxin expression vector was done under BL-3 containment conditions. Plasmid pABI508 was digested with SphI and SalI to remove interleukin-2 (IL-2) coding sequence DNA. The vector (minus IL-2) was gel-purified. Purified SphI x SalI HD-73 inserts were ligated separately to the purified SphI x SalI pABI508 vector DNA. The ligation mixes were used to transform E. coli strain SY327 cells. Correctly assembled hybrid toxin plasmids were identified with Western blots by their ability to produce anti-HD-73 immunoreactive material under control of the constitutively utilized ptox promoter of the diphtheria toxin gene. Synthesis of three size classes of immunoreactive material A hybrid toxin made with p26 SphI x SalI HD-73 DNA gave was detected. immunoreactive protein which migrated between the 116 kd and 180 kd protein standards (computer-generated molecular weight is about 126 kd). A hybrid toxin made with the p151 SphI x SalI HD-73 insert gave immunoreactive protein which migrated between the 84 kd and 116 kd protein standards (computer-predicted molecular weight is about 98 kd). A hybrid toxin made with the p11 SphI x SalI HD-73 insert DNA gave an immunoreactive protein which migrated between the 58 kd and 84 kd protein standards (computer-predicted molecular weight is about 76 kd).

Example 4 - Expression of Hybrid Toxins in E. coli

Under BL-3 containment conditions, *E. coli* cells were grown in LB medium (with or without ampicillin) overnight at 30°C. Cells were collected by centrifugation and treated by one of the following three methods:

- (a) Whole cells were killed with ultraviolet irradiation and kept on ice.
- (b) Periplasmic protein extracts were prepared from whole cells. Cell pellets were resuspended in ice-cold buffer containing 20% sucrose/10 mM Tris-

5

10

15

.....

13

T. W.

20

25

HCl, pH 8.0, 1 mM ethylenediaminetetraacetic acid (EDTA). A volume of cold buffer containing 1.5 mg/ml lysozyme, equal in volume to the volume used for resuspension, was added and incubation proceeded for 20 minutes at 4°C. Cells were removed by centrifugation and the supernatant containing the periplasmic proteins was sonicated and filtered through 0.45 μM filters. Filtered extract was frozen. The majority of hybrid toxin molecules in this extract should lack the diphtheria toxin leader sequence (amino acids -1 to -25) (Murphy [1985] supra) which should be clipped during secretion into the periplasmic space (Murphy, John R., U.S. Patent No. 4,675,382).

(c) Whole-cell extracts were prepared by disruption with a French Press (French pressure cell-laboratory hydraulic press) as follows. Cell pellets were resuspended in ice-cold buffer containing 20% glycerol/50 mM Tris-HCl, pH 7.4/1mM EDTA/1 mM dithiothreitol (DTT)/approximately 1 mM phenylmethylsulfonyl fluoride (PMSF). Cells were disrupted twice with the French Press at 12,000 to 14,000 psi. Cell extracts were frozen. The hybrid toxins should be a mixed population of molecules with respect to the presence of the diphtheria toxin leader sequence (amino acids -1 to -25) since some molecules were likely not secreted.

<u>Example 5 – Purification of Hybrid Toxin</u>

An immunoadsorbent resin was constructed by coupling an equine polyclonal diphtheria toxin antibody (Connaught Laboratories, Swiftwater, PA) to cyanogen bromide (CNBr)-activated SEPHAROSETM 4B (Pharmacia Fine Chemicals, Piscataway, NJ) by following the latter manufacturer's procedure. Briefly, 3 g of lyophilized CNBractivated SEPHAROSETM was cycled into and repeatedly washed with 1 mM HCl. The resulting swollen gel was then washed with coupling buffer (0.5 M NaCl and 0.1 M NaHCO₃, pH 8.3). An aliquot of the diphtheria toxin antibody corresponding to 60 mg was suspended in coupling buffer at a final concentration of 5 mg protein to 5 ml buffer. The SEPHAROSETM and antibody solution were then combined and allowed to

5

10

15

1.4

£ 20

25

incubate at room temperature for 2 hours with end over end mixing. Following the incubation period, the resin was briefly centrifuged (1000 xg x 15 min) and the supernatant was removed. Residual unoccupied reactive groups on the resin matrix were blocked by the addition of 0.2 M glycine, pH 8.0 and allowing to incubate as before. Finally, the immunoadsorbent was washed sequentially in high and low pH buffers (coupling buffer and a buffer comprised of 0.1 M NaCl and 0.1 M NaHCO₃, pH 4). This wash was repeated 4 times to ensure that ionically bound free ligand was removed. This procedure resulted in an overall coupling efficiency of 95%. The prepared immunoadsorbent contained 5.7 mg ligand per ml resin. The immunosorbent was pre-equilibrated with loading buffer (100 mM Tris-Cl, pH 7.4, 20% glycerol, 1 mM Na₂EDTA, 1 mM PMSF, 0.1% nonidet P-40 (NP-40) and 0.1 mM DTT) at 4°C prior to chromatography.

All of the following steps were performed at 4°C unless otherwise noted. The disrupted cell pellet containing the hybrid toxin was partially solubilized by the addition of NP-40 to a final concentration of 0.1% (v/v) to promote dissolution of hydrophobic aggregates. An aliquot of the partially solubilized material, corresponding to 50 mg total protein, was incubated with a slurry of the resin corresponding to 0.5 ml SEPHAROSETM for 3 hr with end over end mixing. Non-specifically bound material was removed from the resin by repeatedly cycling it into wash buffer (100 mM Tris-Cl, pH 7.4, 20% glycerol, 0.2% NP-40 and 0.1% cholic acid). This was followed by successive washes in 0.1 M Tris-Cl to remove all traces of detergent. Finally, the hybrid toxin was eluted by a short incubation with 4 M guanidine-HCl in 0.1 M Tris-Cl, pH 7.4. This fraction was then dialyzed exhaustively against a buffer containing 20 mM Tris-Cl, pH 7.4, 0.1 M NaCl and 0.25 mM reduced glutathione to promote proper refolding.

Example 6 - Insertion of Toxin Gene Into Plants

The novel genes coding for the novel insecticidal toxins, as disclosed herein, can be inserted into plant cells using the Ti plasmid from *Agrobacter tumefaciens*. Plant cells can then be caused to regenerate into plants (Zambryski, P., Joos, H., Gentello, C., Leemans, J., Van Montague, M. and Schell, J [1983] Cell 32:1033-1043). A particularly

10

5

15

:: s._#

100

‡ 20

25

useful vector in this regard is pEND4K (Klee, H.J., Yanofsky, M.F. and Nester, E.W. [1985] Bio/Technology 3:637-642). This plasmid can replicate both in plant cells and in bacteria and has multiple cloning sites for passenger genes. The toxin gene, for example, can be inserted into the <u>Bam</u>HI site of pEND4K, propagated in <u>E. coli</u>, and transformed into appropriate plant cells.

Example 7 - Cloning of Novel B. thuringiensis Genes Into Baculoviruses

The novel genes of the invention can be cloned into baculoviruses such as *Autographa californica* nuclear polyhedrosis virus (AcNPV). Plasmids can be constructed that contain the AcNPV genome cloned into a commercial cloning vector such as pUC8. The AcNPV genome is modified so that the coding region of the polyhedrin gene is removed and a unique cloning site for a passenger gene is placed directly behind the polyhedrin promoter. Examples of such vectors are pGP-B6874, described by Pennock et al. (Pennock, G.D., Shoemaker, C. and Miller, L.K. [1984] Mol. Cell. Biol. 4:399-406), and pAC380, described by Smith et al. (Smith, G.E., Summers, M.D. and Fraser, M.J. [1983] Mol Cell. Biol. 3:2156-2165). The gene coding for the novel protein toxin of the invention can be modified with BamHI linkers at appropriate regions both upstream and downstream from the coding region and inserted into the passenger site of one of the AcNPV vectors. Other baculoviruses can be used, e.g., Spodoptera exigua nuclear polyhedrosis virus (SeNPV) and Heliothis zea nuclear polyhedrosis virus (HzNPV). Each of these viruses is specific for its own host with little activity for other insects (i.e., SeNPV will infect Spodoptera exigua but not Heliothis zea, and vice versa).

Example 8 - Propagation of Viruses

The viruses are propagated by infecting the appropriate larvae. This can be accomplished by direct application of inoculum to the surface of diet cups and placing fourth instar larvae on the diet cups as described by Maruniak (Maruniak, J.E. [1986] The Biology of Baculoviruses, Vol. 1, pp. 129-1;75, R.R. Granados and B.A. Federici, eds., CRC Press). Larvae are then harvested at six days post infection and NPV isolated as follows. The larvae are collected, homogenized and filtered through cheesecloth.

10

5

15

H. H. H.

20

30

The filtrate is then centrifuged for 15 minutes at 8,000 xg. The resulting pellet is resuspended in buffer that contains 0.01 M Tris-HCl pH 7.8 and 1.0 mM EDTA, (TE buffer). The suspension is layered onto a 20-90% sucrose gradient and centrifuged for 60 min at 100,000 xg. The polyhedra, localized as a defined band at approximately 60%, is removed and diluted in TE buffer. The polyhedra are then isolated by centrifugation for 30 min at 10,000 xg.

The purified polyhedral pellet is resuspended in TE buffer and alkali extracted with an equal volume of 0.2 M Na₂CO₃ pH 10.9, 0.17 M NaCl, and 1.0 mM EDTA. The extraction is allowed to proceed for 60 min at room temperature with continuous mixing. The larval occluded virus alkali liberated or LOVAL are isolated by centrifugation and a 20-90% sucrose gradient at 100,000 xg for 60 min. These represent single, double or multiply embedded virions. All bands are recovered, diluted into TE buffer and centrifuged at 100,000 xg for 60 min. The resulting pellet is resuspended in TE buffer containing 1.0 mM PMSF.

The polypeptide components of the SeNPV and HzNPV LOVAL fractions are analyzed by polyacrylamide gel electrophoresis (PAGE) in the presence of sodium dodecyl sulfate (SDS) by the method of Laemmli (Laemmli, U.K., [1970] Nature [London] 227:680-685). The molecular weights determined from the relative electrophoretic mobilities are shown in Table 5. Following the above procedures, we identified thirteen and fourteen polypeptides for the HzNPV and SeNPV LOVAL preparations, respectively.

A bioassay of these preparations demonstrated minimal infectivity of the SeNPV LOVAL in *Heliothis zea* larvae. The converse was also found to be true; the infectivity of HzNPV LOVAL in *Spodoptera exigua* was limited.

Example 9 - Construction of Hybrid Virus

Virulence/specificity of baculoviruses is conferred by fusogen components (recognition fusogens) in the virion envelope. These recognition fusogens are proteins apparently having dual functions of receptor binding and promoting the fusion of membranes. Using known techniques for alteration of the target recognition of Epstein-

i L

20

15

5

10

30

Barr virus with re-associated Sendai virus envelopes (Shapiro, I.M. et al. [1982] Science 219:1225-1228; Volsky, D.J. et al. [1980] Proc. Natl. Acad. Sci. U.S.A. 77:5453-5457; Volsky, D.J. et al. [1979] Proc. Natl. Acad. Sci. U.S.A. 76:5440-5444) we constructed a hybrid virus by re-associating solubilized envelope proteins from SeNPV LOVAL with HzNPV. The procedure involved suspending the LOVAL fraction in 40 mM Trisacetate pH 8.0 containing 1.0 mM EDTA (TAE buffer). This suspension was incubated with octyl glucoside 1:2 (w/w) at 37°C for 4 hr with continuous shaking. Insoluble proteins were removed by centrifugation for 60 min at 100,000 xg. The supernatant containing the solubilized viral proteins was combined with purified HzNPV LOVAL 1:1 (w/w). The detergent was removed by dialysis at 4°C for 24 hr with 3 changes of TAE buffer. The hybrid virus was isolated by centrifugation for 60 min at 100,000 xg through a 10% sucrose cushion.

The resultant hybrid virus was then used to infect both *Spodoptera exigua* and *Heliothis zea* larvae. The results of this study are reported in Table 6. These data show that the hybrid HzNPV has activity against *Spodoptera exigua* that HzNPV does not.

To determine which polypeptide(s) were responsible for conferring virulence, the octyl glucoside extract of SeNPV LOVAL was radiolabeled with ¹²⁵I and combined with unlabeled HzNPV LOVAL. An autoradiogram of the SDS-PAGE of the octyl glucoside extract SeNPV showed three polypeptides present in the soluble fraction. Similar analysis of the hybrid virus showed all three SeNPV proteins to be associated with the HzNPV hybrid. The relative molecular weights of these polypeptides as determined by electrophoretic mobility are shown in Table 7.

We have demonstrated an alteration of NPV host range following construction of a hybrid virus. We conclude that one of the proteins contained in the octyl glucoside extract confers virulence for *Spodoptera exigua* to HzNPV. Thus, we have demonstrated that it is possible to confer virulence from one occluded NPV to another through reassociation of envelope proteins.

Example 10 – Construction of a Hybrid Toxin Using NPV Fusogenic Protein to Replace Bacillus thuringiensis Recognition Protein

Construction of the hybrid virus demonstrates that the proteins in the envelope of the NPV are responsible for altering the virulence. We have identified the three putative proteins (fusogens) involved with this recognition and purified them for determination of individual contribution to the recognition event necessary for the observed alteration in virulence. This determination can be accomplished by constructing three different hybrid viruses with the three individual purified proteins isolated from octylglucoside fraction and HzNPV, as previously described. These are bioassayed individually to determine which hybrid virus confers virulence. The protein responsible for recognition (the recognition fusogen) so identified can be purified and the amino acid sequence determined from reverse phase HPLC purified tryptic fragments of the protein. The amino acid sequence can be used to construct oligonucleotide probes which can be used to identify and isolate the gene that codes for the recognition fusogen from a gene library that is made to the viral DNA by standard molecular genetic techniques. The identified and isolated DNA then can be sequenced to define the open reading frame that codes for the protein. The DNA coding for the recognition fusogen can be cloned into the hybrid toxin construct in place of the B. thuringiensis recognition sequence using techniques described frequently.

It is well known in the art that the amino acid sequence of a protein is determined by the nucleotide sequence of the DNA. Because of the redundancy of the genetic code, i.e., more than one coding nucleotide triplet (codon) can be used for most of the amino acids used to make proteins, different nucleotide sequences can code for a particular amino acid. Thus, the genetic code can be depicted as follows:

Phenylalanine (Phe)	TTK	Histidine (His)	CAK
Leucine (Leu)	XTY	Glutamine (Gln)	CAJ
Isoleucine (Ile)	ATM	Asparagine (Asn)	AAK
Methionine (Met)	ATG	Lysine (Lys)	AAJ
Valine (Val)	GTL	Aspartic acid (Asp)	GAK

Key: Each 3-letter deoxynucleotide triplet corresponds to a trinucleotide of mRNA, having a 5'-end on the left and a 3'-end on the right. All DNA sequences given herein are those of the strand whose sequence correspond to the mRNA sequence, with thymine substituted for uracil. The letters stand for the purine or pyrimidine bases forming the deoxynucleotide sequence.

A = adenine

G = guanine

C = cytosine

T = thymine

X = T or C if Y is A or G

X = C if Y is C or T

Y = A, G, C or T if X is C

Y = A or G if X is T

W = C or A if Z is A or G

W - C if Z is C or T

Z = A, G, C or T if W is C

Z = A or G if W is A

QR = TC if S is A, G, C or T; alternatively

OR = AG if S is T or C

J = A or G

K = T or C

L = A, T, C or G

M = A, C or T

20

The above shows that the novel amino acid sequence of the subject proteins can be prepared by equivalent nucleotide sequences encoding the same amino acid sequence of the protein. Accordingly, the subject invention includes such equivalent nucleotide sequences. In addition it has been shown that proteins of identified structure and function may be constructed by changing the amino acid sequence if such changes do not alter the protein secondary structure (Kaiser, E.T. and Kezdy, F.J. [1984] Science 223:249-255). Thus, the subject invention includes mutants of the amino acid sequence depicted herein which do not alter the protein secondary structure, or if the structure is altered, the biological activity is retained to some degree.

Materials and Methods Used in the Biochemical Analysis of Hybrid Toxins

Materials

The CF-1 cell line, derived from *Choristoneura fumiferana*, was obtained from the Canadian Forestry Research Laboratories (Dr. S. Sohi, Sault Ste. Marie, Ont., Canada). Nicked diphtheria toxin was purchased from Calbiochem (San Diego, CA), and radioisotopes (¹⁴C-leucine and ¹⁴C-NAD) from DuPont/NEN (Boston, MA) at specific activities of 308 and 600 mCi/mmol, respectively. HD-73 *Bacillus thuringiensis* toxin crystals were isolated by NaBr gradient centrifugation. All other chemicals and reagents were of the highest commercially available purity.

Methods

Cell Culture

25

30

CF-1 cell culture stocks were maintained at 28°C in 75 cm² T-flasks with Grace's insect medium (GIBCO, Compton, CA) supplemented with 10% fetal bovine serum, 2 mM L-Glutamine and 2.7 gm/l tryptose broth powder (DIFCO, Detroit, MI). Cultures were passaged daily by 1:1 splits.

10 Mars 10 Mar

20

Radioiodination

The 64 kd toxic component of HD-73 was produced by digestion of HD-73 crystals (1 mg/ml) dissolved in 50 mM CAPS buffer (pH 11) with trypsin (0.1 mg/ml). Digestions were conducted at 37°C on a shaker bath for 3 hr, followed by dialysis against a 20 mM glycine-Tris buffer (pH 8.5). Radioiodinations were conducted in a reaction mix comprised of 100 µg toxin, 50 µg chloramine-T, 1 mCi of Na¹²⁵I and sufficient volume of 100 mM NaPi buffer, pH 7.0 to give a 1.0 ml final volume. The mixture was reacted at 4°C for 5 minutes, the subjected to centrifugal filtration (Centricon, by Amicon; Danvers, MA) to remove unbound ¹²⁵I.

10

5

Cvanogen Bromide Digestions

To 7 mg of HD-73 64 kd toxin was added 8 ml of 88% formic acid and 212 mg of CNBr. The mixture was reacted for 24 hr at 25°C in the dark, then dialyzed against five 2-1 changes of 20 mM glycine-Tris buffer, pH 8.6.

Binding Assays

CF-1 cells were harvested by centrifugation and resuspended at a concentration of 2.94 x 10⁵/ml in Tyrode's solution (in gm/l: NaCl, 7.0; CaCl₂·2H₂O, 0.2; NaH₂PO₄, 0.2; KCl, 0.2; MgCl₂·6H₂O, 0.1; HEPES, 4.8; glucose, 8.0; pH 6.3) containing 1 mg/ml bovine serum albumin. For binding assays, 450 μl of cell suspension was incubated with 50 μl of unlabeled toxin or CNBr digest at various concentrations for 20 min at 25 °C, then with 25 μl of iodinated toxin for an additional 20 min. The cells were then recovered and washed (3 x 5 ml of 50 mM CAPS buffer, pH 11) by vacuum filtration on Whatman GF/A filter discs, and cell-bound radioactivity was quantitated by liquid scintillation. Control binding was determined as described above but in the absence of competing ligand. Background binding to the filter discs was determined from incubations performed in the absence of cells.

25

EF-2 Ribosylation Assays

30

Elongation factor 2 (EF-2) was extracted from raw wheat germ and partially purified as previously described (Legocki, A.B. [1979] Methods Enzymol. 50:703-712).

¹⁴C-NAD was diluted to a specific activity of 240 mCi/mmol with deionized water. Ribosylation assays were performed in a final volume of 200 µl containing 170 µl of EF-2 (0.8 mg), 20 µl of hybrid toxin or diphtheria toxin (control) and 10 µl of ¹⁴C-NAD. Toxin and EF-2 were incubated at 37°C for 20 minutes, followed by the addition of ¹⁴C-NAD and subsequent incubation for 30 minutes at 37°C. The reaction was stopped by the addition of 3 ml of ice-cold 5% trichloroacetic acid (TCA), and the precipitated protein was collected by vacuum filtration on GF/A filter discs, which were counted by liquid scintillation.

¹⁴C-Leucine Incorporation into Protein in CF-1 Cells

Incubations were typically conducted in a volume of 500 µl containing 450 µl of CF-1 cells suspended in cell medium at a concentration of 5 x 10⁶/ml and 50 µl of hybrid toxin, diphtheria toxin, HD-73 or appropriate buffer control. At varying intervals, 100 μl aliquots were withdrawn and incubated with 10 μl of ¹⁴C-leucine for 30 min. Cells were pelleted by centrifugation, discarding the supernatant. The cell pellet was solubilized by the addition of 200 µl of 0.1 N KOH, and protein was precipitated by the addition of 200 µl of ice-cold 20% TCA. After 15 min on ice, the TCA precipitate was collected by vacuum filtration on Whatman GF/B discs (Whatman Laboratory Products, Clifton, NJ) and washed twice with 3 ml of cold 10% TCA. Filter discs were counted for radioactivity as described elsewhere.

Autoradiograms developed from SDS-PAGE gels of radioiodinated HD-73 demonstrated labeling of the 64 kd active toxin protein produced by trypsin digestion. The specific activity of labeling was estimated to be 3×10^{16} cpm/mol. Figure 2 shows that unlabeled HD-73 competes with the labeled toxin for binding to CF-1 cells with an IC_{50} of 35 µg/ml. In addition, binding of radiolabeled toxin equilibrated rapidly (< 5 min), and was not reversed by wash out procedures. Saturation studies gave an estimate of $> 1 \times 10^6$ binding sites per cell. These findings demonstrate specific binding of the radiolabeled 64 kd tryptic peptide of HD-73 to CF-1 insect cells in culture. The 64 kd component is therefore considered a viable candidate for the binding site recognition portion of a hybrid toxin construct.

5

10

20

H-W H-W

In order to further delineate the binding site recognition domain of the 64 kd toxin, CNBr digestions were performed to generate smaller peptides for analysis. Following dialysis through a 14 kd cutoff membrane, we obtained peptides of 18 and 19 kd molecular weights as evidenced by SDS-PAGE. Binding experiments with CF-1 cells demonstrated that this peptide mixture partially competes for iodinated 64 kd binding (Figure 3). It is therefore likely that the binding domain of HD-73 can be mapped to at least one of these two CNBr-generated peptides.

Figure 4 gives the concentration dependence for diphtheria toxin - stimulated ADP - ribosylation of wheat germ EF-2. Half maximal ribosylation was obtained at a diphtheria toxin concentration of 0.8 ng/ml. The extent of ADP-ribosylation at saturating diphtheria toxin concentrations was quite reproducible in our hands, and was therefore used as an index for quantitating hybrid toxin-catalyzed ribosylation. Figure 5 gives the results for such determinations, showing that quarter- and half-length hybrid toxins are roughly equivalent with respect to their ribosylation capacities, though 5000-fold less potent than diphtheria toxin. However, uncertainty in the relative purity of the hybrid toxin preparation makes the latter comparison approximate, and almost certainly represents a low end estimate of potency.

Figure 6 demonstrates the inhibiting effect of HD-73 toxin on the incorporation of radiolabeled leucine into protein in CF-1 cells. Half-maximal inhibition was obtained at an HD-73 concentration of 40 μ g/ml, in good agreement with the binding data presented above. Additional concurrence between HD-73 binding and inhibition of protein synthesis was established for the time-course and irreversibility of the inhibitory effect.

Incubation of CF-1 cells with quarter- and half-length hybrid toxins results in a slowly developing inhibition of protein synthesis (Figure 7). From the 24-hour exposure data, we estimate a 50-fold increase in potency for the quarter-length and a 100-fold increase for the half-length hybrid toxin over that established for HD-73. The lengthened time-course and increased potency observed for the hybrid toxins indicate a mechanism of action distinct from that of HD-73. Furthermore, diphtheria toxin does not inhibit protein synthesis in CF-1 cells at concentrations up to 200 µg/ml. It is

10

[20

5

therefore unlikely that the inhibition produced by the hybrid toxin preparations is related to either the diphtheria or *B.t.* toxin domains by themselves, as might be the case if these two portions of the hybrid construct dissociated under experimental conditions. Rather, we conclude that these findings demonstrate an inhibitory mechanism unique to the intact hybrid toxins.

The various methods employed in the preparation of the plasmids and transformation of host organisms are well known in the art. These procedures are all described in Maniatis, T., Fritsch, E.F., and Sambrook, J. (1982) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory, New York. Thus, it is within the skill of those in the genetic engineering art to extract DNA from microbial cells, perform restriction enzyme digestions, electrophorese DNA fragments, tail and anneal plasmid and insert DNA, ligate DNA, transform cells, prepare plasmid DNA, electrophorese proteins, and sequence DNA.

The restriction enzymes disclosed herein can be purchased from Bethesda Research Laboratories, Gaithersburg, MD, or New England Biolabs, Beverly, MA. The enzymes are used according to the instructions provided by the supplier.

A subculture of the host containing plasmid p26, also known as pMYC26, is presently on deposit in the Mycogen Corporation Culture Collection at San Diego, California. It was deposited on May 10, 1988, in the permanent collection of the Northern Research Laboratory, U.S. Department of Agriculture, Peoria, Illinois, USA. It was deposited in an *E. coli* host as *E. coli* HB101 (pMYC26)(MR382). It was assigned the deposit number NRRL B-18367. The plasmid can be obtained from the host by use of standard procedures, for example, using cleared lysate-isopycnic density gradient procedures, and the like.

The subject culture was deposited under conditions that assure that access to the culture will be available during the pendency of this patent application to one determined by the Commissioner of Patents and Trademarks to be entitled thereto under 37 CFR 1.14 and 35 USC 122. The deposit will be available as required by foreign patent laws in countries wherein counterparts of the subject application, or its progeny, are filed. However, it should be understood that the availability of a deposit

25

does not constitute a license to practice the subject invention in derogation of patent rights granted by governmental action.

Further, the subject culture deposit will be stored and made available to the public in accord with the provisions of the Budapest Treaty for the Deposit of Microorganisms, i.e., it will be stored with all the care necessary to keep it viable and uncontaminated for a period of at least five years after the most recent request for the furnishing of a sample of the deposit, and in any case, for a period of at least 30 (thirty) years after the date of deposit or for the enforceable life of any patent which may issue disclosing the culture. The depositor acknowledges the duty to replace the deposit should the depository be unable to furnish a sample when requested, due to the condition of the deposit. All restrictions on the availability to the public of the subject culture deposit will be irrevocably removed upon the granting of a patent disclosing it.

the state of the s

Claims

1	1. A hybrid pesticidal protein toxin comprising a cytotoxic agent and a pest gut
2	epithelial cell recognition portion of a protein said cytotoxic agent and said recognition
3	portion not being naturally contiguous.
1	2. The toxin, according to claim 1, wherein said cytotoxic agent is an ADP-
2	ribosylating enzyme.
1	3. The toxin, according to claim 2, wherein said ADP-ribosylating enzyme is
2	diphtheria toxin.
1	4. The toxin, according to claim 1, wherein said cytotoxic agent is a ribosome
2	inactivating enzyme selected from the group consisting of ricin, dianthin, saporin, gelonin,
3	tritin, abrin, and modeccin.
1	5. The toxin, according to claim 1, wherein said cytotoxic agent is a ribosome
2	inactivating enzyme obtainable from a seed selected from the group consisting of barley, rye,
3	corn, and wild bean.
l	6. The toxin, according to claim 3, wherein the diphtheria toxin used is the A
2	fragment of the diphtheria toxin, plus the B fragment of the diphtheria toxin which has been
3	truncated at the carboxyl terminus to remove the eukaryotic recognition region.
l	7. The toxin, according to claim 1, wherein said pesticidal protein toxin is a <i>Bacillus</i>
2	thuringiensis protein toxin.

8. The toxin, according to claim 7, wherein said Bacillus thuringiensis protein toxin

- 2 is expressed by the gene fragment from *Bacillus thuringiensis* Var. *kurstaki* H.D.-73.
 - 9. The toxin, according to claim 1, wherein said cytotoxic agent and pest gut epithelial cell recognition portion of a protein are linked together by a peptide linker of suitable length and amino acid composition to minimize susceptibility to insect protease cleavage.
 - 10. The toxin, according to claim 9, wherein said peptide linker consists of four or less amino acids.
 - 11. The toxin, according to claim 9 wherein said peptide linker does not contain lysine residues.
 - 12. A toxin, according to claim 1, wherein said pest gut epithelial cell recognition portion of a protein is a nuclear polyhedrosis virus recognition fusogen.
 - 13. The toxin, according to claim 12, wherein said nuclear polyhedrosis virus recognition fusogen is linked to a cytotoxic agent by a peptide linker of suitable length and amino acid composition to minimize susceptibility to insect protease cleavage.
- 1 14. The toxin, according to claim 13, wherein said peptide linker consists of four or less amino acids
- 1 15. The toxin, according to claim 12, wherein said peptide linker does not contain 2 lysine residues.

Abstract of the Disclosure

The invention concerns novel hybrid pesticidal toxins. These toxins are expressed as the fusion protein of a chimeric gene. Specifically exemplified is a novel <u>B.t.</u> hybrid toxin. These novel toxins have increased toxicity against target pests. The invention also concerns a process for preparing a hybrid virus having an altered insect host range.

## 

## **DECLARATION (37 CFR 1.63) AND POWER OF ATTORNEY**

As a below-named inventor, I hereby declare that:

My residence, post office address, and citizenship are as stated below next to my name; and

I believe that I am the original, first, and sole inventor (if only one name is listed below), or an original, first, and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled **Novel Hybrid Pesticidal Toxins**, for which a United States Patent application was filed November 30, 1992, Serial No. 07/983,344.

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, §1.56(a).

I hereby claim the benefit under Title 35, United States Code, §120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application(s) in the manner provided by the first paragraph of Title 35, United States Code, §112, I acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, §1.56(a) which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

Application Serial No.

Filing Date

Status (Patented, Pending, Abandoned)

07/187,167

April 28, 1988

Pending

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

I hereby appoint the following persons registered to practice before the Patent and Trademark Office as my attorneys with full power of substitution and revocation to prosecute this application and all divisions and continuations thereof and to transact all business in the Patent and Trademark Office connected therewith:

Roman Saliwanchik, Reg. No. 21,023 David R. Saliwanchik, Reg. No. 31,794 Jeff Lloyd, Reg. No. 35,589 Ted W. Whitlock, Reg. No. P-36,965

I request that all correspondence be sent to:

Jeff Lloyd 2421 N.W. 41st Street, Suite A-1 Gainesville, FL 32606

I further request that all telephone communications be directed to:

Jeff Lloyd 904-375-8100
